- **xd_xml_validate**: validates an XML file using an XML schema as reference.
- **xd_select_schema**: it returns the most recent schema name supported for a given file type and mission

4.2.Reading and writing files

When reading files, the user should be aware that:

- Many of the structures used for reading files contain dynamic data that is allocated within the reading function. In these cases, the memory has to be freed when it is not going to be used any more by calling the suitable function.
- The reading functions for each of the file types, does not read the fixed header. The fixed header could be read independently using the CFI function **xd_read_fhr**.
- When reading the fixed header with **xd_read_fhr**, the schema name is not read (the "schema" element in the output structure **xd_fhr** will be set to "_NOSCHEMA_") . If required, the schema name and version should be read independently with the CFI functions in explorer_file_handling.

When writing files, the user should be aware that:

- The schema name and version can be written in the file in the following ways:
  - Setting the schema name in the "schema" element in the **xd_fhr** structure. When calling the **xd_write_*xxx*** function, the schema name and version will be written in the file. Note that if the schema name is set to "_NOSCHEMA_", the schema attributes will no be written in the file.
  - After writing the file, by calling the function **xf_set_schema** (in explorer_file_handling). Note that the CFI function **xd_select_schema** allows to get the default schema name with which the file to be written is compliant.

4.3. Memory usage

Note: due to the implementation of the third-party library handling XML files, large amount of memory may be needed by an application handling (reading or writing) a file with many entries. Therefore the user is recommended to perform handling of large files on computers equipped with adequate memory resources. If these resources are not available, the user has to properly configure virtual memory and take into account long execution times. In extreme cases, due to platform limitation or operating system settings, the operation may fail. In order to give an indication, a restituted orbit file covering a period of 10 days and a time interval between OSVs of 30 sec contains 28800 OSVs and its size on disk is about 14MB. The memory usage peak during the writing of such file is about 215MB.

5. LIBRARY INSTALLATION

For a detailed description of the installation of any CFI library, please refer to [GEN_SUM].

6. LIBRARY USAGE

The EO_DATA_HANDLING software library has the following dependencies:

- Other EOCFI libraries: EO_FILE_HANDLING (See [F_H_SUM]).
- Third party libraries:
  - POSIX thread library: libpthread.so (Note: this library is normally pre-installed in Linux and MacOS platforms. For Windows platforms, pthread.lib is included in the distribution package, with license LGPL);
  - GEOTIFF, TIFF, PROJ, LIBXML2 libraries (these libraries are included in the distribution package. Their usage terms and conditions are available in the file "TERMS_AND_CONDITIONS.TXT" which is part of the distribution package).

The following is required to compile and link a Software application that uses the EO_DATA_HANDLING software library functions (it is assumed that the required EOCFI and third-part libraries are located in directory *cfi_lib_dir* and the required header files are located in *cfi_include*, see [GEN_SUM] for installation procedures):

1) include the following header files in the source code:

   - explorer_data_handling.h (for a C application)

2) use the following compile and link options:

   Linux and MacOS platforms:

   -I*cfi_include_dir* -L*cfi_lib_dir* -lexplorer_data_handling

   -lexplorer_file_handling -lgeotiff -ltiff -lproj -lxml2 -lm -lc -lpthread

   Windows platforms:

   /I *"cfi_include_dir"* /libpath:*"cfi_lib_dir"* libexplorer_data_handling.lib

   libexplorer_file_handling.lib libgeotiff.lib libtiff.lib libproj.lib libxml2.lib pthread.lib Ws2_32.lib

All functions described in this document have a name starting with the prefix `xd_`

To avoid problems in linking a user application with the `EO_DATA_HANDLING` software library due to the existence of names multiple defined, the user application should avoid naming any global software item beginning with either the prefix `XD_` or `xd_`.

It is possible to call the following CFI functions from a user application.

Error Handling Functions

Notes about the table:

- To transform the extended status flag returned by a CFI function to either a list of error codes or a list of error messages, the enumeration value (or the corresponding long value) described in the table must be used
- The error handling functions have no enumerated values

Whenever available it is strongly recommended to use enumeration values rather than integer values.

6.1.Usage hints

Every CFI function has a different length of the Error Vector, used in the calling I/F examples of this SUM and defined at the beginning of the library header file. In order to provide the user with a single value that could be used as Error Vector length for every function, a generic value has been defined (XD_ERR_VECTOR_MAX_LENGTH) as the maximum of all the Error Vector lengths. This value can therefore be safely used for every call of functions of this library.

6.2.General Enumerations

The aim of the current section is to present the enumeration values that can be used rather than integer parameters for some of the input parameters of the EO_DATA_HANDLING routines, as shown in the table below. The enumerations presented in [GEN_SUM] are also applicable.

7.7.xd_read_doris

7.7.1.Overview

The **xd_read_doris** CFI function reads DORIS Navigator files for Cryosat and Sentinel 3 (the function detects automatically the type of file).

The description of S3 DORIS can be found in CNES doc CO-SP-D0-EA-16222-CN (note: it is an internal CNES document).

The following items must be considered:

- Since the file does not contain orbit numbering information, the orbit number is set to 1 at the first OSV and increased at each ANX.
- During reading operation, the following issues are taken into account:

1) A packet is discarded and a warning is raised with the packet number if at least one of the following conditions is detected:

   - CRC error (only for Sentinel 3);

   - quality field = 0xFFFFFFFF (packet not valid);

   - OSV time going back or repeated.

2) It is assumed that, within the file, packets with same APID are sorted by sequence counter and the sequence counter is increasing by 1. If it is not increased by one a warning is raised with the packet id where the difference was found.

3) If a gap is found in the file (that is, the separation between one OSV and the following one is more than 1.5 times the nominal rate of the DORIS files, which is 10 seconds), a warning is raised with the packet id where the gap was found.

4) Apart from packets discarded due to conditions listed in 1), all OSVs contained in the packets will be loaded in the output data structure, regardless of any other non-nominal condition (as the ones described in 2) and 3)).

The calling interface of the **xd_read_doris** CFI function is the following (input parameters are underlined):

7.45.xd_read_sp3

7.45.1.Overview

The **xd_read_sp3** CFI function reads a Standard Product 3 C (SP3-C) File.

The description of the output struct (xd_sp3_file) can be found in table 3.

The detailed description of the SP3 file can be found in section 9.20.

The following items must be considered when reading a SP3 file:

1) SP3 file does not provide information about the orbit number.
2) The xd_read_sp3 function extracts file common information and only Orbit State Vectors for satellites (see output struct xd_sp3_file).
3) The following time conversions are performed, depending on the SP3 file time system:

   - If time system is GPS (identifier GPS), GALILEO (identifier GAL) or QZSS (identifier GZS), the times are converted to TAI, taking into account that TAI time is equal to GPS/GALILEO/QZSS time plus 19 seconds. Since no time correlation is provided, TAI-UTC and UT1-UTC differences are set to zero.

   - If time system is GLONASS (identifier GLO), the times are converted to UTC, taking into account that UTC time is equal to GLONASS time minus 3 hours. Since no time correlation is provided, TAI-UTC and UT1-UTC differences are set to zero.

   - If time system is TAI (identifier TAI) or UTC (identifier UTC), the times are taken as they are in the corresponding time reference system. Since no time correlation is provided, TAI-UTC and UT1-UTC differences are set to zero.
4) The Orbit State Vectors are recorded in output struct following the satellite order found in SP3 file. For example, if the identifiers of the satellites are G01G02G04, the corresponding OSVs information are (taking into account that this information is stored in the field osv_rec_sp3 of xd_sp3_file):

   - For G01: osv_rec_sp3[0]

   - For G02: osv_rec_sp3[1]

   - For G04: osv_rec_sp3[2]

   Note that the position in array corresponds to position in satellite list, not in the satellite identifier number.
5) A warning is raised if at least one of the following conditions is detected:
   - OSV with time going back
   - OSV with repeated time

7.45.2.Calling interface

The calling interface of the **xd_read_sp3** CFI function is the following (input parameters are underlined):

7.54.6.Executable program

An XML file can also be validated using the executable program **xml_validate.** It can be called from a Unix shell as:

xml_validate -file filename

[**-sch** schema_filename] [**-log** log_filename]

[-help] [-v]

[-show]

Note that:

- Order of parameters does not matter.
- Bracketed parameters are not mandatory.
- [-v] option for Verbose mode (default is Silent).
- [-show] displays the inputs of the function and the results.
- The filename is validated using the schema_filename if it is provided. If not, the default schema is used (the one in the root element of the file).
- The validation log is stored in the log_filename. By default the standard output is used.

Example:

xml_validate **-file** ../../data/CRYOSAT_XML_OSF

-sch ../../../../schemas/public/CS_OPER_MPL_ORBSCT_01.00.XSD

-log log_file_exe **-show**

7.56.xd_orbit_file_decimate

7.56.1.Overview

The **xd_orbit_file _decimate** adds capability to configure position interpolator according to user need (decimation).

The decimation is performed in the orbit file structure. This way user has two options using the output of this function:

1.to write a new orbit file and use this file to initialize the orbit id.

2.To initialize directly the orbit id with the new structure.

The fucntion works as follows:

·First and last state vectors in input list are copied to output list.

·Using the input decimation delta (D), and being t0 the time of the first state vector of the input list, the state vectors whose time is closer to time t=t0+k*D (k = 1, 2...n, t0<t<tn) are copied to output list.

7.56.2.Calling interface

The calling interface of the **xd_orbit_file_decimate** CFI function is the following (input parameters are underlined):

```
#include <explorer_data_handling.h>
{
 xd_fhr fhr_in, fhr_out;
 xd_orbit_file osv_in, osv_out;
 double decimation_delta_time;
 long ierr[XD_NUM_ERR_ORBIT_FILE_DECIMATE];
 status = xd_orbit_file_decimate(&fhr_in, &osv_in,
                                 decimation_delta_time,
                                 &fhr_out, &osv_out,

7.61.xd_orbit_file_diagnostics

7.61.1.Overview

The **xd_orbit_file_diagnostics** CFI function computes diagnostics data related to an orbit file. Such data can be analysed to detect problems in the file or identify fragments of the file to be discarded. The following information is returned:

- Size of the interval covered by the file.
- Times of first and last OSV.
- Number and interval of GAPs in the file.
- Number and indexes of duplicated OSVs, i.e. OSVs whose time is the same as the one of previous OSV; i.e. if *time_osv1* and *time_osv2* are the times of one OSV and the following one respectively, the duplicated OSVs fulfill the following condition:

  $|time\_osv2 - time\_osv1| < diagnostics\_settings.duplicated\_osv\_threshold$
- being *diagnostics_settings* one input parameter to the function (check section 7.61.2).
- Number and indexes of the OSVs going back in time, i.e. OSVs whose time is in the past with respect to the previous one; i.e. the OSVs are not identified as duplicated OSVs and fulfill the following conditions:

  1) $time\_osv2 - time\_osv1 < 0$.

  2) $|time\_osv2 - time\_osv1| > diagnostics\_settings.duplicated\_osv\_threshold$
- Number and indexes of OSVs with inconsistent orbit number (i.e. OSVs whose number is not correlated with its neighbours OSVs).
- Number and indexes of OSVs with non-equally spaced OSVs (i.e. OSVs that are separated from its neighbours a different step from the one expected).

For DORIS files only EF OSVS are checked, because they are the ones used by orbit initialization.

7.61.2.Calling interface

The calling interface of the **xd_orbit_file_diagnostics** CFI function is the following (input parameters are underlined):

```

- FFS_1: compliant with v1.0 of File Format Standard (e.g. Cryosat, SMOS);
- FFS_2: compliant with v2.0 of File Format Standard (e.g. Sentinel Missions, EarthCARE).

This version of this EOCFI SW is able to handle (read and/or write) files compliant to older schemas. The following table presents the list of all schema versions. For each version, the “Supp. CFI“ column shows how such file is handled:

- N indicates that the version is not supported for neither reading nor writing.
- Y: indicates that the version is supported for both reading and writing (the used schema depends on the applicable File Format Standard).
- R: indicates that the version is supported only for reading.

Note that the writing functions create files with the version labeled with “Y”.

Note also that for those files that can be written by the CFI, the written version depend on the satellite mission (For reading, the files can be read independently of the mission).

9. FILES FORMAT SPECIFICATION

This section presents the formats for all the files used by the Earth Observation CFI software. These formats correspond to the last schema versions indicated in section 8.

The files used by the CFI can be:

- External: Files generated and/or used for the CFI software and other external facilities.
- Internal: Files used only in the CFI for configuration purposes.

All internal files are written in ASCII, with XML syntax. Following the usual format for the Earth Observation Files, the file contains both:

- A header: It is divided in a fixed header and optionally a variable header. The format for the fixed header is common to all Earth Observation Files and can be seen in Error: Reference source not found.
- A data block containing the input/output data of the functions.
- The general structure for a file will be:

```
<?xml version = "1.0" encoding = "UTF-8"?>
<Earth_Explorer_File>
   <Earth_Explorer_Header>
      <Fixed_Header>
      ...
      </Fixed_Header>
      <Variable_Header>
      ...
      </Variable_Header>
   </Earth_Explorer_Header>

   <Data_Block type="xml">
   ...
   </Data_Block type>

</Earth_Explorer_File>
```

9.1.Fixed Header

9.1.1.Format

The Fixed Header is an XML structure. Many of its fields are redundant with the File Name elements, but are present in more readable form in the Fixed Header, whereas in File Name they are more compact for obvious reasons. Its format is described in the followig tables:

Table 151: Fixed Header Structure

Tag name	type	Attribute	C Format	Description

File_Name	string	-	%s	It is a repetition of the Logical File Name, i.e. the File Names excluding the extension. This allows this field to be independent from the storage in 1 complete file or 2 separate files for Header and Data Block
File_Description	string	-	%s	A 1-line description of the File Type. Each Mission shall define the list of official file descriptions (per File Type).
Notes	string	-	%s	Multi-lines free text. This can be used for any type of comment, relevant that instance of the file.

9.2.Predicted Orbit files

9.2.1.Format

1. Fixed Header: For the fixed header format, refer to Error: Reference source not found

2. Variable Header: It contains the information for of the reference frame of the state vectors in the file and the reference time for time recomputations. The format is in Table 154.

3. Data Block: It consists in a set of structures described in the tables below:

Table 154: Predicted Orbit File. Variable_Header

Tag name	type	Attribute	C Format	Description
Ref_Frame	string	-	%s	Reference frame for the state vectors in the file. It can be one of the following values: BAR_MEAN_2000 HEL_MEAN_2000 GEO_MEAN_2000 MEAN_DATE TRUE_DATE EARTH_FIXED BAR_MEAN_1950 QUASI_MEAN_DATE PSE_TRUE_DATE PSEUDO_EARTH_FIXED
Time_Reference	String	-	%s	It is used as time reference when, due to an inconsistency with other time correlations, times associated to the state vector have to be recomputed. See xo_orbit_init_file in [ORBIT_SUM] for more details. It can be one of the following values:TAIUTC UT1

Note to Reference Frame: the main usage of the Orbit Library is to support geo-location. As a consequence an Earth-Fixed frame is the natural reference frame to use, end-to-end. On the other hand, accurate conversion between inertial and earth-fixed frames happens only when polar motion data is available, more precisely when the time_id has been previously initialized with a IERS Bulletin.

Therefore, when polar motion data is not available, the user is recommended to initialize the orbit id by providing Orbit files with Earth-Fixed frame data (orbit state vectors), and to compute geo-location information in Earth-Fixed. This provides accurate computations. For any other usage the user shall be aware of the consequences and accept small inaccuracies, In particular:

·initializing the orbit id with inertial orbit data, and computing inertial parameters, is also supported and is accurate;

·initializing the orbit id with earth-fixed orbit data, and computing inertial parameters (or vice-cersa), leads to slightly inaccurate computations and should be avoided unless ignoring polar motion is acceptable.

UT1	date		%s	UT1 date and time of OSV, in ASCII standard time format, including time reference and micro-seconds
Absolute_Orbit	integer		%+06ld	absolute orbit counter This counter is incremented by one unit from a record to the next. It must be dif- ferenciated with the real absolute orbit number on which the state vector really belongs i.e : if the Z value of the OSV is >= 0 then "real" absolute orbit number equal the absolute orbit counter if the Z value of the OSV is < 0 then "real" absolute orbit number equal the absolute orbit counter minus 1.
X	real	m	%+012.3lf	X position in earth-fixed coordinate system
Y	real	m	%+012.3lf	Y position in earth-fixed coordinate system

VX	real	m/s	%+012.6lf	X velocity in earth-fixed coordinate system

VY	real	m/s	%+012.6lf	Y velocity in earth-fixed coordinate sys-tem
VZ	real	m/s	%+012.6lf	Z velocity in earth-fixed coordinate system
Quality	string	string	%13s	Values is/are TBD. This parameter is added to keep format compatibility with the DORIS Precise Orbit File Format. Default (“not used”) value is “0000000000000”

Attitude_Angles	Structure (see Table 176)	-	-	Pitch, roll and yaw angles for a given time. When angles are used to create an attitude file, 6 decimal digits are written (for quaternions 9 decimal digits are written, see Table 175).

Table 175: Attitude File. List of Quaternions Data

Tag name	type	Attribute	C Format	Description
Quaternions	Structure (see Table 177)	-	-	Set of quaternions for a given time. When quaternions are used to create an attitude file, 9 decimal digits are written. Having this number of digits reduces significantly pointing errors. Note: the quaternions represent a transformation that transforms a vector in Reference_Frame into a vector expressed in the frame given in the field Attitude_File_Type

9.17.TLE File

The format of the TLE files are described in: http://celestrak.com.

A few TLE items (Name, Designator, Catalog Number) are part of the NORAD Satellite Catalog (SATCAT) and are assigned by NORAD after satellite launch.

The EOCFI SW uses, for each pre-defined satellite ID, a set of default SATCAT items as defined in table Table 232: NORAD Identifiers for satellites.

For non pre-defined satellite IDs (i.e. "Default" Satellites, see section 7.2 of [GEN_SUM], the NORAD SATCAT items can be set directly via the satellite configuration file, see section 9.9).

The user can change such default values by using function xl_set_tle_sat_data (see section 7.48 of Error: Reference source not found).

It can be either:
1 - an absolute path
2 - a relative path
3 - a file name
For case 2, attitude initialization functions search for the file in the path relative to the directory where the Attitude Definition file is located. If not found, in the path relative to current working directory.
For case 3, attitude initialization functions search for the file in the directory where the Attitude Definition file is located. If not found, in the current working directory.
