4 INTRODUCTION

4.1 Functions Overview

This software library contains the CFI functions required to perform accurate computation of pointing parameters from and to a satellite for various types of targets.

It includes a set of functions to initialize the attitude of the platform and the instruments. The values provided by these functions are later used by all the other functions of the library.

A detailed description of each function is provided in Section 7.

Please refer also to:

[MCD] for a detailed description of the time references and formats, coordinate systems, parameters and models used in this document

[GEN_SUM] for a complete overview of the CFI, and in particular the detailed description of the *Id* concept and usage and the error handling functions

4.1.1 Attitude Data Flow

The following figure shows the tipical data flow for the attitude functions. First, the different transformations between the various reference frames are initialised. Then, given the spacecraft position, the attitude is calculated:

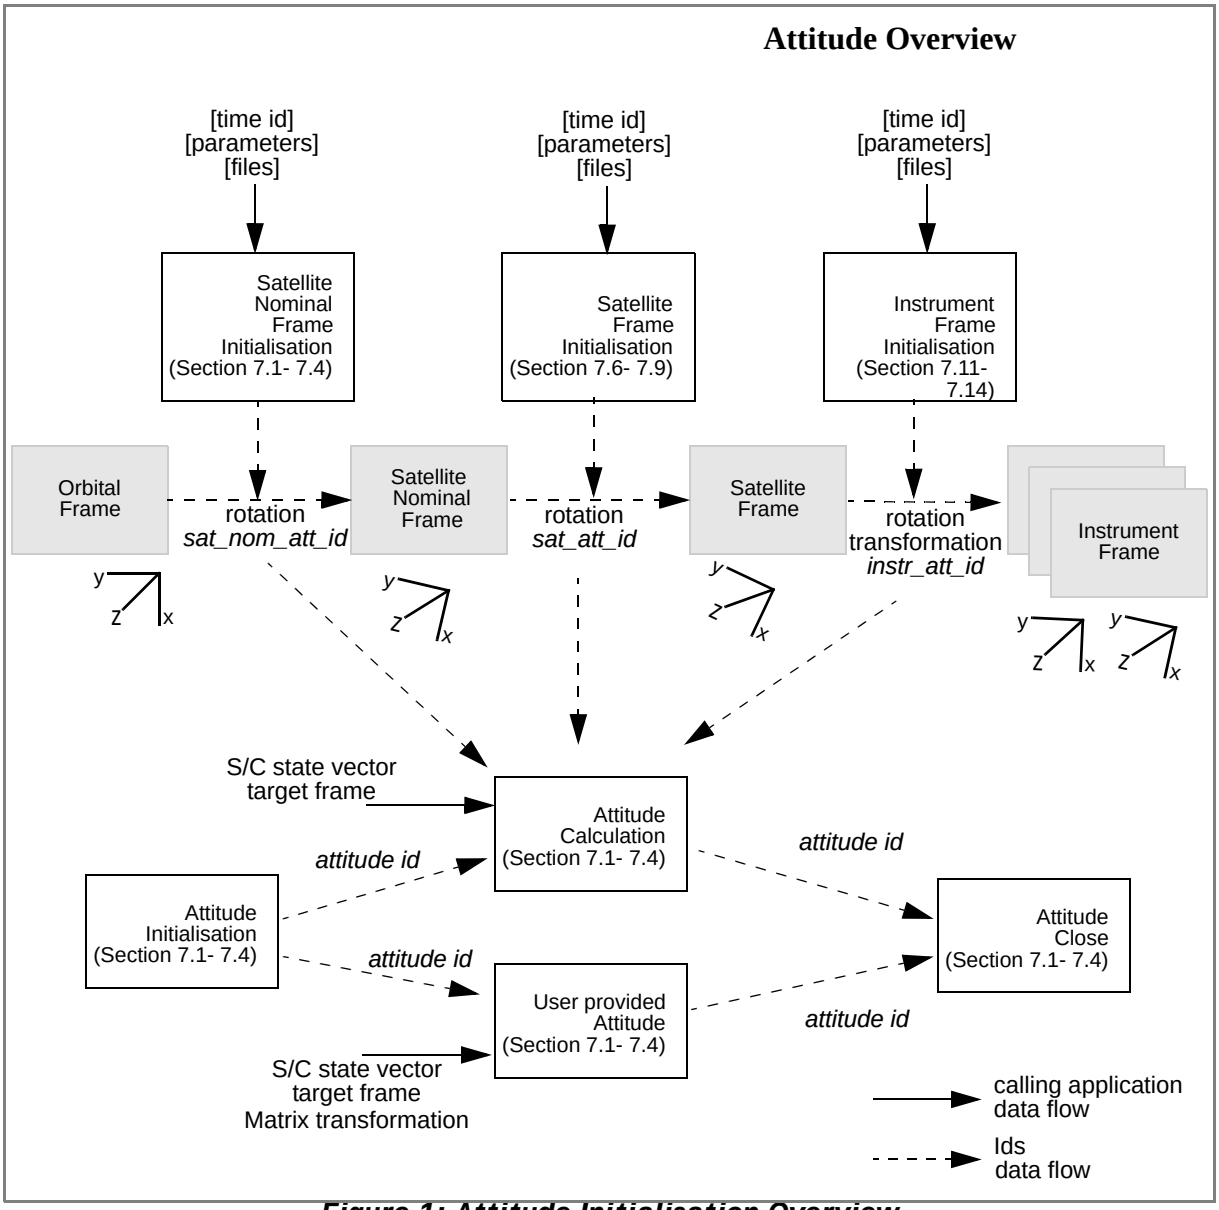

Figure 1: Attitude Initialisation Overview

Each different transformation can be initialised with different models:

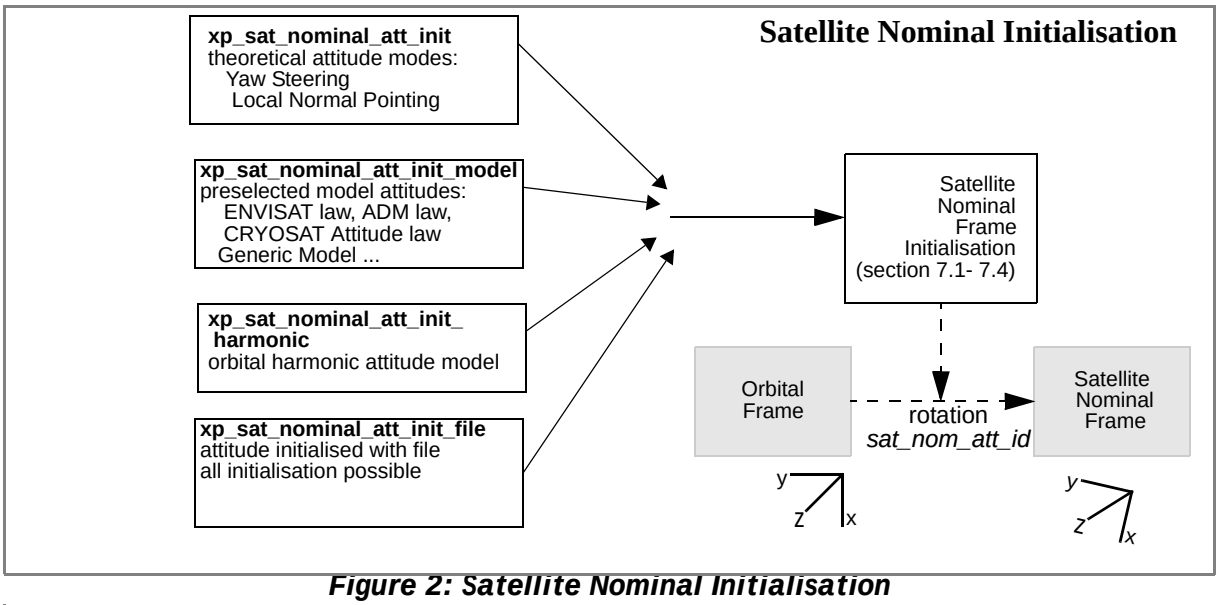

Figure 2: Satellite Nominal Initialisation

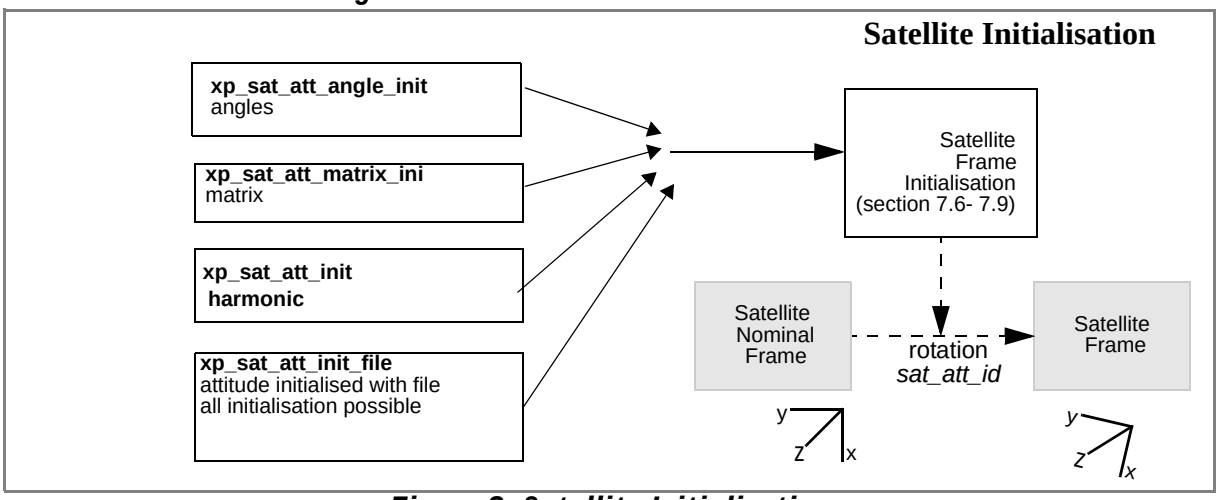

Figure 3: Satellite Initialisation

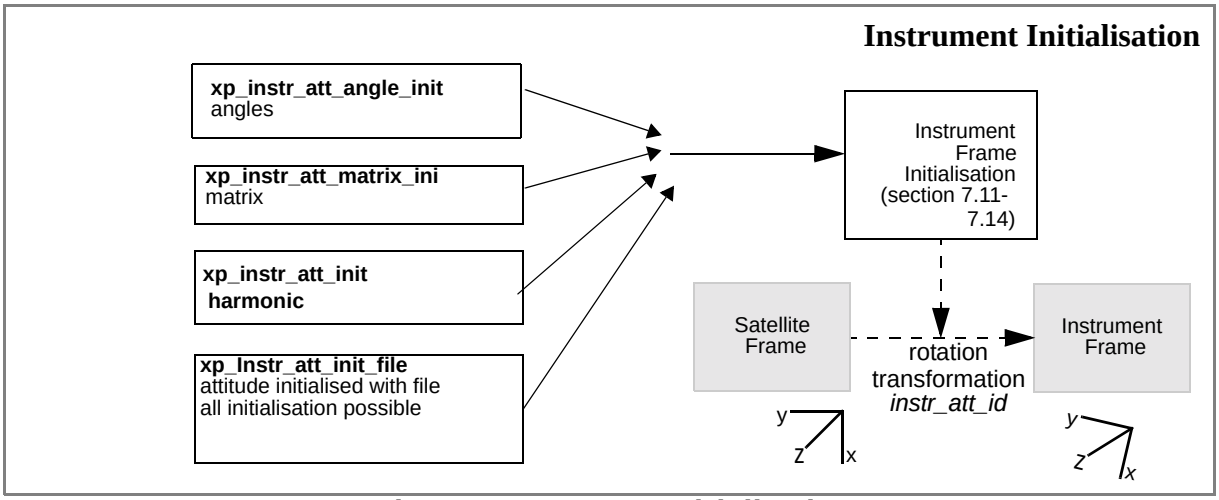

Figure 4: Instrument Initialisation

4.1.2 Geolocation Routines Data Flow

The following figure shows the tipical data flow for the geolocation routines functions. First, the attitude should be calculated, and, if needed, the refraction and Digital Elevation Models initialised.

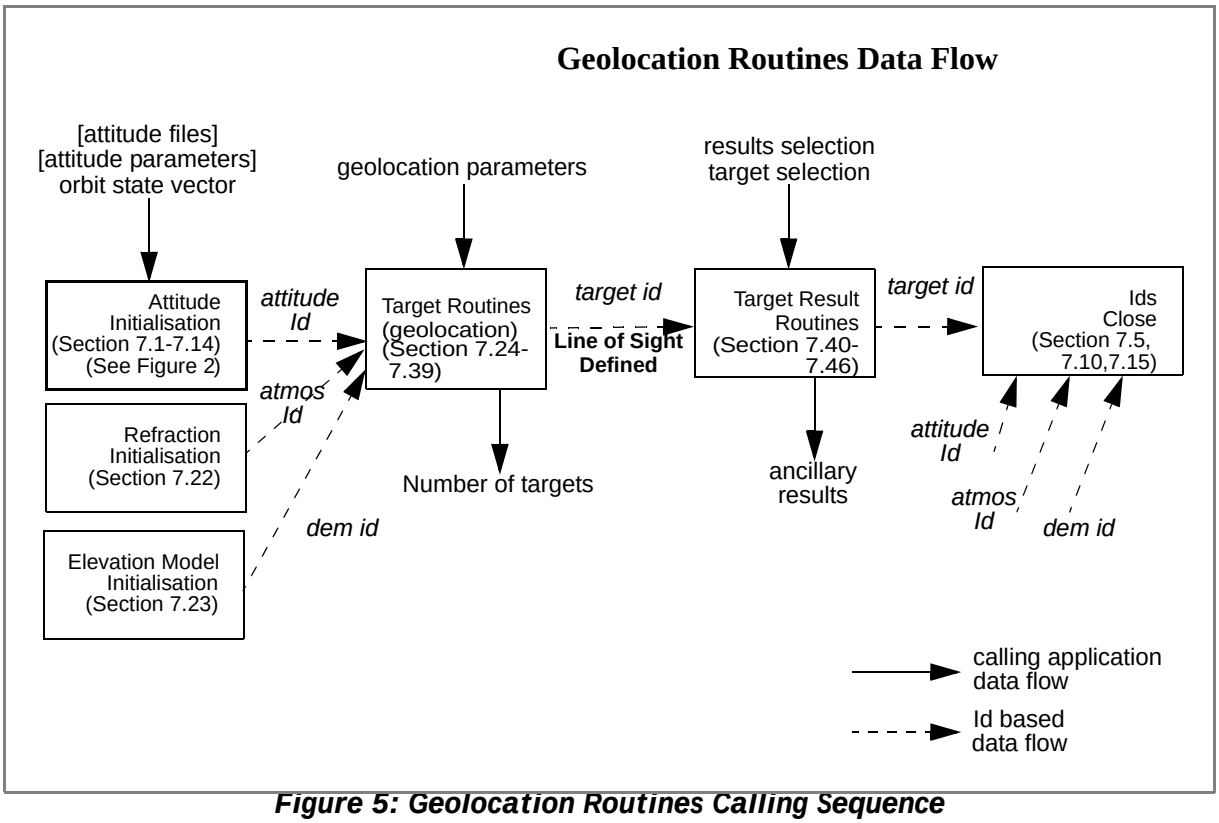

Figure 5: Geolocation Routines Calling Sequence

The table below and the diagrams on the next pages describe the various **xp_target_<function>.**

xp_target_ <function>	Description
xp_(multi)_target_ inter	It calculates the intersection point(s) of the line of sight defined by an elevation and an azimuth angle expressed in the input Attitude frame, with a surface(s) located at a certain geodetic alti-tude(s) over the Earth.
xp_(multi)_target_ travel_time	It calculates the point of the line or sight from the satellite (defined by an elevation and an azimuth angle expressed in the selected Attitude Frame) at a given travel time(s) along the (curved) line of sight.
xp_target_ground _range	It calculates the location of a point that is placed on a surface at a certain geodetic altitude over the Earth, that lays on the plane defined by theS/C position, the nadir and a reference point, and that is at a certain distance or ground range measured along that surface from that reference point. xp_target_range	It calculates the location of a point that is placed on a surface at a certain geodetic altitude over the Earth, that is seen from the S/C on a line of sight that forms a certain azimuth angle in the input Atti-tude frame, and that is at a certain range or slant-range from the S/C.
xp_target_range_r ate	It calculates the location of a point that is placed on a surface at a certain geodetic altitude over the Earth, that is at a certain range from S/C, and whose associated Earth-fixed target has a certain range-rate value.
xp_target_tangent	It calculates the location of the tangent point over the Earth that is located on the line of sight defined by an elevation and azimuth angles expressed in the input Attitude frame.
xp_target_altitude	It calculates the location of the tangent point over the Earth that is located on a surface at a certain geodetic altitude over the Earth and that is on a line of sight that forms a certain azimuth angle in the input Attitude frame.
xp_target_star	It calculates the location of the tangent point over the Earth that is located on the line of sight that points to a star defined by its right ascension and declination coordinates.
xp_target_generic	The cartesian state vector of the target is taken as an input.
xp_target_tangent _sun	It calculates the location of the tangent point over the Earth that is located on the line of sight that points to the Sun
xp_target_tangent _moon	It calculates the location of the tangent point over the Earth that is located on the line of sight that points to the Moon
xp_target_station	It calculates the most relevant observation parameters of the link between the satellite and a ground station
xp_target_drs	It calculates the most relevant observation parameters of the link between the satellite and a Data Relay Satellite (DRS).

As it can be seen from the list of functions, there are some functions that calculate several targets (xp_multi_target_xxxx). The number of targets found by the functions is returned through the interface.

In addition to these “user” targets, two other categories of targets can be defined, “LOS” targets and “DEM” targets.

4.1.2.1 LOS targets

The idea is to get information about all the ray path points computed by a specific target routine along the Line of Sight (LOS) trajectory.

For every target routine, the output parameter num_los_target will return the number of points in the path.

It applies when the variable "target_type" is equal to XP_LOS_TARGET_TYPE.

1. Start point of LOS

The spacecraft position (Instrument CS) shall be considered as the start point for the LOS path.

2. Stop point of LOS

The stop point for the LOS path will be different depending on the selected target function; nominally it will be the resulting target point.

- xp_target_inter and xp_multi_target_inter: 1st or 2nd intersection point (Point corresponding to the last altitude for the multi_target routine)
- xp_target_ground_range: Target point

    - The tangent point if tangent height > Refraction Model Maximum Height
- xp_target_altitude: Point at selected altitude
- xp_target_star: Two different cases to consider depending on whether refraction is selected or not:
  - No refraction mode: Tangent point
  - Refraction mode:
    - The 2nd intersection point with a surface located at Refraction Model Maximum Height (geodetic altitude) over the Earth if tangent height <= Refraction Model Maximum Height

- xp_target_tangent_moon: Tangent point

4.1.2.2 DEM targets

A DEM Target is defined as the intersection of a line of sight with the Earth Surface defined using a digital elevation model (DEM).

A DEM Target is calculated using as line of sight the LOS targets that has been computed previously with a target routine (Note that such LOS consist in a polygonal line, no necessarily a straight line). Consequently, to get a DEM target it is neccessary to follow these steps:

- Initialize the DEM model using the xp_dem_init routine and a configuration file (Section 7.52).
- One call to the target routine for getting the LOS targets.
- One call to the target extra routine requesting the DEM target.

The digital elevation model of the Earth consists in a set of points defining a grid for which a measure of the altitude over the Earth reference elipsoid is given. The altitude of the points within each cell of the grid is computed by the CFI using a bilinear interpolation with the points of the corner of the cell. Details about the bilinear algorithm used to compute the intersection can be seen in [LOS_ALG].[LOS_ALG]

5 LIBRARY INSTALLATION

For a detailed description of the installation of any CFI library, please refer to [GEN_SUM].

6 LIBRARY USAGE

Note that to use the EXPLORER_POINTING software library, the following other CFI software libraries are required:

- `EXPLORER_FILE_HANDLING` (See [F_H_SUM]).
- `EXPLORER_DATA_HANDLING`
- `EXPLORER_LIB` (See [LIB_SUM]).

It is also needed to have properly installed in the system the following external GPL libary:

- `LIBXML2` (See [GEN_SUM]).

and the POSIX thread library:

- libpthread.so (pthread.lib for WINDOWS)

To use the EXPLORER_POINTING software library in a user application, that application must include in its source code either:

- `explorer_pointing.h` (for a C application)
- `explorer_pointing.inc` (for a ForTran application under SOLARIS)
- `explorer_pointing_win.inc` (for a ForTran application under Windows 9X/NT/2000)

To link correctly this application, the user must include in his linking command flags like (assuming *cfi_lib_dir* and *cfi_include_dir* are the directories where respectively all CFI libraries and include files have been installed, see [GEN_SUM] for installation procedures):

- SOLARIS/LINUX:

```
-Icfi_include_dir -Lcfi_lib_dir -lexplorer_pointing
                                -lexplorer_lib
                                -lexplorer_data_handling
                                -lexplorer_file_handling
                                -lxml2 -lpthread
```

- WINDOWS:

```
/I "cfi_include_dir"  /libpath:"cfi_lib_dir"
                                libexplorer_pointing.lib
                                libexplorer_lib.lib
                                libexplorer_data_handling.lib
                                libexplorer_file_handling.lib
                                libxml2.lib pthread.lib
```

- MacOS:

```
-Icfi_include_dir -Lcfi_lib_dir -lexplorer_pointing
                                 -lexplorer_lib
                                 -lexplorer_data_handling
                                 -lexplorer_file_handling
                                 -lpthread
                                 -framework libxml
                                 -framework libiconv
```

All functions described in this document have a name starting with the prefix xp_

To avoid problems in linking a user application with the EXPLORER_POINTING software library due to the existence of names multiple defined, the user application should avoid naming any global software item beginning with either the prefix XP_ or xp_.

It is possible to call the following CFI functions from a user application.

Notes about the table:

- To transform the extended status flag returned by a CFI function to either a list of error codes or list of error messages, the enumeration value (or the corresponding long value) described in the table must be used
- The error handling functions have no enumerated values

Whenever available **it is strongly recommended to use enumeration values rather than integer values**.

6.1 Usage hints

The runtime performances of some of the CFI functions are improved to a large extent if they are called two consecutive times keeping constant some of their inputs.

Nevertheless, although the user may not need to call the CFI functions two consecutive times with the same inputs, there are internal functions that are actually called in those conditions, and thus improving the runtime performances of the former.

Thus, the runtime improvement is achieved with any sequence of calls to those CFI functions, not only with a sequence of calls to the same function.

In fact, the time, position, velocity, acceleration vectors, AOCS and mispointing angles do not need to keep exactly constant as long as the difference between two consecutive calls lays within the following thresholds:

- Time: 0.0864 microsec
- Position vector: 0.6e-3 m
- Velocity vector: 0.6e-6 m/s
- Acceleration vector: 0.6e-9 m/s^2
- AOCS: 5e-9 deg
- Mispointing angles: 5e-9 deg
- Mispointing angles-rate: 5e-12 deg
- Mispointing angles-rate-rate: 5e-15 deg

Every CFI function has a different length of the Error Vector, used in the calling I/F examples of this SUM and defined at the beginning of the library header file. In order to provide the user with a single value that could be used as Error Vector length for every function, a generic value has been defined (XP_ERR_VECTOR_MAX_LENGTH) as the maximum of all the Error Vector lengths. This value can therefore be safely used for every call of functions of this library.

6.2 General Enumerations

The aim of the current section is to present the enumeration values that can be used rather than integer parameters for some of the input parameters of the EXPLORER_POINTING routines, as shown in the table below. The enumerations presented in [GEN_SUM], [F_H_SUM] and [LIB_SUM] are also applicable.

7 CFI FUNCTIONS DESCRIPTION

The following sections describe each CFI function.

The calling interfaces are described for both C and ForTran users.

Input and output parameters of each CFI function are described in tables, where C programming language syntax is used to specify:

- Parameter types (e.g. long, double)
- Array sizes of N elements (e.g. param[N])
- Array element M (e.g. [M])

ForTran users should adapt the tables using ForTran syntax equivalent terms:

- Parameter types (e.g. long <=> INTEGER*4, double <=>REAL*8)
- Array sizes of N elements (e.g. param[N] <=> param (N))
- Array element M (e.g. [M] <=> (M+1))

7.1 xp_sat_nominal_att_init

7.1.1 Overview

The **xp_sat_nominal_att_init** CFI function initialises the AOCS mode for a given satellite. The initalised mode will be stored in the *sat_nom_trans_id* output structure.

7.1.2 Calling Interface

The calling interface of the **xp_sat_nominal_att_init** CFI function is the following (input parameters are underlined):

```
#include <explorer_pointing.h>
{
      long aocs_mode;
      xp_sat_nom_trans_id sat_nom_trans_id = {NULL};
      long ierr[XP_NUM_ERR_NOM_ATT_INIT_DEF], status;

      status = xp_sat_nominal_att_init(&aocs_mode,
                                       &sat_nom_trans_id, ierr);
}
```

The `XP_NUM_ERR_SAT_NOM_ATT_INIT` constant is defined in the file *explorer_pointing.h*.

For ForTran programs the declaration and calling procedure is as follows (input parameters are underlined, note that the C preprocessor must be used because of the presence of the `#include` statement):

```
#include <explorer_pointing.inc>
      INTEGER*4 AOCS_MODE
      INTEGER*4 IERR(XP_NUM_ERR_SAT_NOM_ATT_INIT), STATUS

      STATUS = XP_SAT_NOMINAL_ATT_INIT(SAT_ID, AOCS_MODE, IERR)
```

7.1.3 Input Parameters

Table 5: Input parameters of xp_sat_nominal_att_init function

C name	C type	Array Element	Description (Reference)	Unit (Format)	Allowed Range

This table also indicates the type of message returned, i.e. either a warning (WARN) or an error (ERR), the cause of such a message and the impact on the performed calculation.

The table is completed by the error code and value. These error codes can be obtained by translating the error vector returned by the **xp_sat_nominal_att_init** function by calling the function of the EXPLORER_POINTING software library **xp_get_code** (see [GEN_SUM])

The calling interface of the **xp_sat_nominal_att_init_model** CFI function is the following (input parameters are underlined):

```
#include <explorer_pointing.h>
{
      long model_enum;
      double model_param[XP_NUM_MODEL_PARAM];
      xp_sat_nom_trans_id sat_nom_trans_id = {NULL};
      long ierr[XP_NUM_ERR_SAT_NOM_ATT_INIT_MODEL], status;

      status = xp_sat_nominal_att_init_model(&model_enum,
                                             model_param,
                                            &sat_nom_trans_id, ierr);
}
```

The `XP_NUM_ERR_SAT_NOM_ATT_INIT_MODEL` and `XP_NUM_MODEL_PARAM` constants are defined in the file *explorer_pointing.h.*

7.2.3.1 Generic Model description

The generic model builds the reference frames from the specified direction vectors.

The model parameters are:

- first_axis: It can be any of {+/-XP_X_AXIS, +/-XP_Y_AXIS, +/-XP_Z_AXIS}

- first_target: It can be any of {XP_SUN_VEC, XP_MOON_VEC, XP_EARTH_VEC, XP_NADIR_VEC, XP_INERTIAL_VEL_VEC, XP_EF_VEL_VEC, XP_INERTIAL_TARGET_VEC, XP_EF_TARGET_VEC, XP_SC_EF_VEL_VEC, XP_ORBIT_POLE}
- first_vector[3]: contains either dummies, [long, lat, alt] (if first_target= XP_EF_TARGET_VEC) or [ra, decl, parallax] (if first_target=XP_INERTIAL_TARGET_VEC})
- second_axis: It can be any of {+/-XP_X_AXIS, +/-XP_Y_AXIS, +/-XP_Z_AXIS}
- second_target: : It can be any of {XP_SUN_VEC, XP_MOON_VEC, XP_EARTH_VEC, XP_NADIR_VEC, XP_INERTIAL_VEL_VEC, XP_EF_VEL_VEC, XP_INERTIAL_TARGET_VEC, XP_EF_TARGET_VEC, XP_SC_EF_VEL_VEC, XP_ORBIT_POLE}
- second_vector[3]: contains either dummies, [long, lat, alt] (if first_target= XP_EF_TARGET_VEC) or [ra, decl, parallax] (if first_target=XP_INERTIAL_TARGET_VEC})

It is necessary to define a convention for each target type (e.g, always from Satellite to XXX):

- XP_SUN_VEC: Unit direction vector from Satellite to Sun
- XP_MOON_VEC: Unit direction vector from Satellite to Moon
- XP_EARTH_VEC: Unit direction vector from Satellite to Earth centre (opposite to Satellite Position Vector)
- XP_NADIR_VEC: Unit direction vector from Satellite to Nadir point
- XP_INERTIAL_VEL_VEC: Inertial Velocity vector (in TOD)
- XP_EF_VEL_VEC: Earth Fixed Velocity vector
- XP_INERTIAL_TARGET_VEC: Unit direction vector from Satellite to a target defined by a given [ra, decl, parallax]. The annual parallax is used in case we are pointing to a close object (for instance, the Moon), in order to get the distance. For stars, parallax=0 shall be used, meaning infinite distance. Units: degrees
- XP_EF_TARGET_VEC: Unit direction vector from Satellite to a target defined by a given [long, lat, alt]
- XP_SC_EF_VEL_VEC: Satellite Earth Fixed Velocity vector
- XP_ORBIT_POLE: Unit direction vector normal to the orbital plane (computed as the cross product of the Satellite Position vector and its Velocity vector)

With these parameters, the calculation is done as follows:

- Compute the unit direction vector specified by first_target
  - Assign the calculated first target vector to the first axis vector
- Compute the unit direction vector specified by second_target
  - Cross-product of the first axis vector and the second target vector
  - Assign the resulting vector to the second axis vector
  - Complete the right-handed frame

The following are some examples:

3. Sun-Fixed Reference Frame

- model_param = {XP_X_AXIS, XP_SUN_VEC, 0.0, 0.0, 0.0, XP_Z_AXIS, XP_EARTH_VEC, 0.0, 0.0, 0.0}

  Then:

- X-axis = Unit vector from Satellite to Sun (Sun Vector)
- Z-axis = Unit cross product: X-axis x (Unit vector from Satellite to Earth (Earth Vector))
- Y-axis = Z-axis x X-axis (completing the right-handed frame)

4. Yaw Steering Mode

- model_param={-XP_Z_AXIS, XP_NADIR_VEC, 0.0, 0.0, 0.0, XP_X_AXIS, XP_EF_VEL_VEC, 0.0, 0.0, 0.0}

  Then:

- Z-axis = -(Unit vector from Satellite to Nadir (Nadir Vector))
- X-axis = Unit cross product: Z-axis x (Earth-Fixed Velocity Vector)
- Y-axis = Z-axis x X-axis (completing the right-handed frame)

7.2.4 Output Parameters

This table also indicates the type of message returned, i.e. either a warning (WARN) or an error (ERR), the cause of such a message and the impact on the performed calculation.

The table is completed by the error code and value. These error codes can be obtained by translating the error vector returned by the **xp_sat_nominal_att_init_model** function by calling the function of the EXPLORER_POINTING software library **xp_get_code** (see [GEN_SUM])

7.3 xp_sat_nominal_att_init_harmonic

7.3.1 Overview

The **xp_sat_nominal_init_harmonic** CFI function initialises the satellite orbital to satellite nominal attitude mispointing angles for a given satellite with a user-provided set of values. The initalised values will be stored in the *sat_nom_trans_id* output structure.

The xp_attitude and xp_change_frame functions will then compute the values as follows:

$$\begin{aligned} attitudeangle = {} & bias + 1stsincoef \cdot \sin\left(\frac{angle \cdot 2\pi}{360}\right) + 1stcoscoef \cdot \cos\left(\frac{angle \cdot 2\pi}{360}\right) \\ & + 2ndsincoef \cdot \sin\left(\frac{2 \cdot angle \cdot 2\pi}{360}\right) + 2ndcoscoef \cdot \cos\left(\frac{2 \cdot angle \cdot 2\pi}{360}\right) \\ & + 3rdsincoef \cdot \sin\left(\frac{3 \cdot angle \cdot 2\pi}{360}\right) + 3rdcoscoef \cdot \cos\left(\frac{3 \cdot angle \cdot 2\pi}{360}\right) \\ & + \ldots \end{aligned}$$

The calling interface of the **xp_sat_att_init_file** CFI function is the following (input parameters are underlined):

```
#include <explorer_pointing.h>
{
      xl_time_id time_id = {NULL};
      long n_files, time_init_mode, time_ref;
      char **attitude_file *auxiliary_file;
      double time0, time1;
      double val_time0, val_time1;
      xp_sat_trans_id sat_trans_id = {NULL};
      long ierr[XP_NUM_ERR_SAT_ATT_INIT_FILE], status;

      INTEGER*4 ORBIT0, ORBIT1
      CHARACTER*LENGTH_NAME ATTITUDE_FILE(NUM_FILES), AUXILIARY_FILE

      STATUS = XP_SAT_ATT_INIT_FILE(SAT_ID, N_FILES,

7.17.3 Input Parameters

The **xp_sat_att_init_file** CFI function has the following input parameters:

Table 62: Input parameters of xp_sat_att_init_file function

C name	C type	Array Element	Description (Reference)	Unit (Format)	Allowed Range
time_id	xl_time_id*	-	Structure that contains the time correlations.	-	-
n_files	long *	-	Number of reference data files	-	> 0
attitude_file	char **	-	Filenames of the reference data files. In case multiple files are used, the files should be time ordered. The supported Attitude File formats are the Generic Attitude File (described in [DAT_SUM]) and Star Tracker files. If multiple files are used, Generic Attitude Files and Star Tracker files cannot be given to the function as part of the same list. When using Star-Tracker files, the function assumes that all the input files belong to the same Star-Tracker. As a consequence of this assumption only the Star-Tracker identifier of the first file provided in the list is read. Note that the Star-Tracker identification number should be either 1, 2 or 3 (no internal check is performed)	-	-
auxiliary_file	char **	-	Filename of an auxiliary file containing the Star-Tracker misalignement matrices (the format must be the same as the attitude file given in function xp_instr_att_init_file)	-	-
time_init_mode	long *	-	Flag for selecting the time range of the initialisation.	-	Select either: · XP_SEL_TIME · XP_SEL_FILE
time_ref	long *	-	Time reference ID	-	Complete
time0	double*	-	If: *time_init_mode=XP_SEL_TIME* Start of the time range defined by [time0,time1]	Decimal days (Processing format)	[-18262.0,36524.0]

Table 62: Input parameters of xp_sat_att_init_file function

C name	C type	Array Element	Description (Reference)	Unit (Format)	Allowed Range

It is possible to use enumeration values rather than integer values for some of the input arguments:

- Time Reference ID: time_ref. See [GEN_SUM].
- Time Init Mode ID: time_init_mode. See current document, table 3.

The possible causes of error are:

- The sat_trans_id was not initialised.
- The sat_trans_id initialisation does not allow the use of this function.

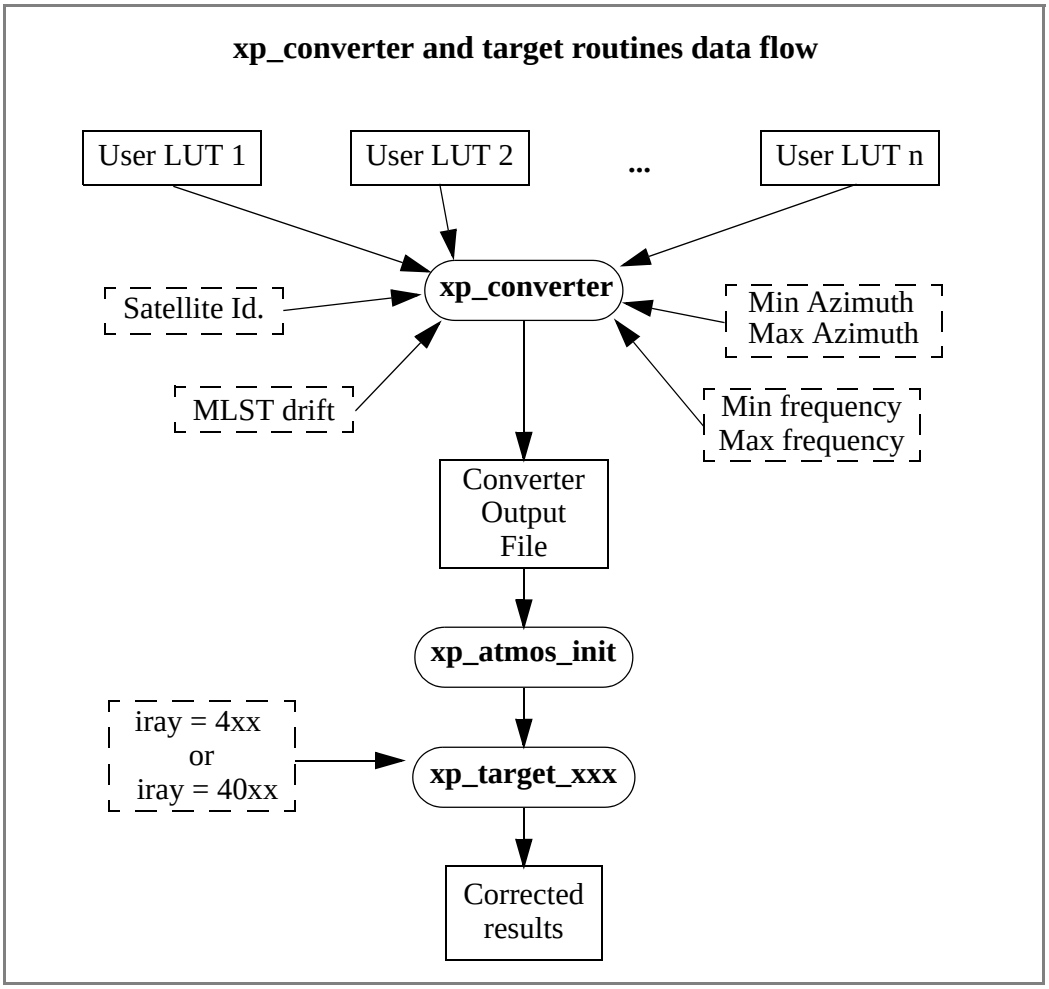
7.83 xp_converter

7.83.1 Overview

Before calling a target CFI function using iray = 400 or iray = 4000 (user's predefined refraction ray tracing models), the atmosphere model should be initialised using a user's file containing the description of the atmosphere. This file can be generated using the executable program **xp_converter.**

xp_converter allows the user to select different atmosphere models to obtain different corrective functions, each of them with a given latitude band and a given validity time. The output file name should be defined in the enviromental variable XP_USER_REF_CONV_FILE_NAME, before running **xp_converter**. If the variable is not defined the function returns an error.

The overall data flow of **xp_converter** and **xp_target_xxx** for a user predefined reraction ray tracing model is as follows:



7.83.2 Calling interface

xp_converter shall be called from a UNIX or WINDOWS shell as follows:

```
xp_converter -sat satellite_id
             -cif User_LUT_1
             [-cif User_LUT_2]
              ...
             [-cif User_LUT_n]
             -min_az min_azimuth
             -max_az max_azimuth
             -min_freq min_frequency
             -max_freq max_frequency
             -mlst_dr mlst_drift
             [-v]
             [-xl_v]
             [-xo_v]
             [-xp_v]
             [-help]
```

taking into account the following considerations:

- Order of parameters does not matter
- Bracketed parameters are not mandatory
- *xl_v* for *explorer_lib* verbose mode.
- *xo_v* for *explorer_orbit* verbose mode.
- *xp_v* for *explorer_pointing* verbose mode.
- *v* for Verbose mode for the 3 libraries (default is silent).
- *help* option will print the above text on stderr (no execution).

7.83.4 Output

In addition to the **xp_converter** output file, some intermediate output files are produced with data that can be plotted. They are named *interm_outp_file_xx.dat* (where *xx* is the number of the LUT file) and *interm_outp_file_av.dat* (for the average) and they can be plotted with **gnuplot** (in a UNIX shell).

For **xp_target_xxx** CFI function, the selection of the user atmosphere determines the correction to be applied to the parameters of the unrefracted tangent point (tangent altitude, etc.). The following table defines the relation between the iray input parameter and the selected corrective function:

Table 302: iray input vs corrective function.

IRAY	Mnemonic	Description
400	PP_LUT_REF	Average User-defined Corrective function
401	PP_LUT_REF + 1	First User-defined Corrective function
...		
400 + n	PP_LUT_REF + n	Last User-defined Corrective function (*n* being the number of LUT input files for xp_converter)
4000	PP_LUT_REF_N	Average User-defined Corrective function (No refraction in Sun and Moon related parameters).
4001	PP_LUT_REF_N + 1	First User-defined Corrective function (No refraction in Sun and Moon related parameters).
...		

Table 302: iray input vs corrective function.

IRAY	Mnemonic	Description
4000 + n	PP_LUT_REF_N + n	Last User-defined Corrective function (No refraction in Sun and Moon related parameters).

8 LIBRARY PRECAUTIONS

The following precaution shall be taking into account when using EXPLORER_POINTING library:

- When a message like

  EXPLORER_POINTING >>> ERROR in *xp_function*: Internal computation error # *n*

  or

  EXPLORER_POINTING >>> WARNING in *xp_function*: Internal computation warning # *n*

  appears, run the program in ***verbose*** mode for a complete description of warnings and errors and call for maintenance if necessary.

9 KNOWN PROBLEMS

The following precautions shall be taken into account when using the CFI software libraries:

Table 303: Known problems

CFI library	Problem	Work around solution
xp_target_travel_time/ xp_multi_target_travel _time	Parameter “travel time-rate” not used in the calculations.	
xp_target_reflected/ xp_target_extra_specu lar_reflection	Not implemented yet (only interface defined).	
xp_converter	No available yet with the updated interfaces
